

PERSONA PLACE RECOMMENDER

Start with a type of person. Find the corridors that matter.

BEGINNER → INTERMEDIATE

DATA + FILTERING

OPTIONAL: MAP / LLM / MCP

THE IDEA

Imagine a business wants to reach a particular group of people. Instead of checking every corridor manually, you could build a tool where the user chooses an audience and gets a list of relevant corridors.

THE QUESTION TO SOLVE

“Where should I look if I want to reach this audience?”

The goal is to turn audience information into a shortlist of corridors and then add enough context to explain why those corridors are relevant.

WHAT THE DATA GIVES YOU

- Audience information: 55 audience segments help describe which groups are more relevant to each corridor.
- Corridor information: name, neighborhoods, character and other context.
- Activity information: relative activity across morning, midday, evening, late night and weekend periods.
- Places: cafés, grocery stores, schools, hospitals, event venues, nightlife and other place categories.
- Anchors and special context: important places such as transit, campuses, hospitals, malls or stadiums.

THE MINDSET

Start with the person you are trying to reach. Then work backwards to the places that matter.

EXAMPLE 03 / UNDERSTAND THE PROBLEM

1. WHY WOULD SOMEONE NEED THIS?

The dataset tells you a lot about corridors, but a user may start with a much simpler thought: “I care about this kind of person. Where are the best places to look?”

Starting point	What the tool should help answer
I care about families	Which corridors are more relevant for families?
I want morning commuters	Which corridors score strongly for morning commuters?
I want hospital workers	Which corridors are relevant to hospital workers, and what is around them?
I want several audiences	Which corridors are relevant to more than one audience?

2. START WITH ONE SIMPLE QUESTION

“Given an audience I care about, which corridors should I explore?”

Start with one audience. Once the first version works, add more context or support more questions.

3. A SIMPLE WAY TO THINK ABOUT IT

Choose an audience	Find relevant corridors	Compare the results	See what is around them	Recommend + explain
--------------------	-------------------------	---------------------	-------------------------	---------------------

The first version can be ordinary programming: read the data, find the selected audience, rank corridors and display the result. You do not need AI to make the basic idea useful.

4. WHAT SHOULD THE RESULT LOOK LIKE?

Corridor	Audience relevance	Why it might matter
Corridor A	High	Strong audience signal + useful morning context
Corridor B	High	Strong audience signal + relevant places nearby
Corridor C	Medium	Worth comparing with other corridors

These examples are illustrative. Your actual values and corridor names should come from the provided dataset.

EXAMPLE 03 / USE THE DATA

5. WHICH PARTS OF THE DATA CAN HELP?

Audience	The audience you want to understand. Examples include morning commuters, family households, hospital workers, office routines and study groups.
Audience score	A score showing how relevant an audience is to a corridor. Higher means stronger relevance; it is not headcount.
Activity	Relative activity across different parts of the day, such as morning, midday, evening, late night and weekend.
Places	Existing place categories in the corridor, such as cafés, grocery stores, schools, hospitals, even and nightlife.
Corridor context	Character, neighborhoods, anchors and other details that help explain the result.
Business fit	Information about which business formats appear more or less suitable, if that is useful for your recommendation.

6. YOU DO NOT NEED EVERYTHING

A common mistake is trying to use every field in the dataset. Start with the information that helps answer your audience question.

Audience	Corridor	Activity	Places
----------	----------	----------	--------

Then add anchors, business-fit information, a map or other context only when it improves the recommendation.

7. WHAT DOES AN “AUDIENCE SCORE” MEAN?

The data gives each corridor a score for different audience segments. Think of it as a signal for comparison, not a count of people.

Score	Simple meaning	Use it to
Higher	More relevant to this audience	Move a corridor higher in your shortlist
Lower	Less relevant to this audience	Move it lower or investigate why

EASY WAY TO THINK ABOUT IT

“This corridor looks more relevant to the audience I selected.”

EXAMPLE 03 / BUILD THE RECOMMENDER

8. WHAT COULD A SIMPLE VERSION LOOK LIKE?

PERSONA → PLACE FINDER

Target audience: [Morning Commuters ▼]

TOP MATCHES

1 Corridor A Audience relevance: HIGH

Morning activity: HIGH Key context: Transit / offices

2 Corridor B Audience relevance: HIGH

Morning activity: MEDIUM Key context: Local business district

3 Corridor C Audience relevance: MEDIUM

Click a corridor to see places and context.

The exact design is up to you. The goal is to make the recommendation easy to understand.

9. MAKE THE RECOMMENDATION EXPLAINABLE

A useful tool should not only say “Corridor A is #1.” It should also give the user enough context to understand why.

SHOW	EXAMPLE
Audience	High relevance for morning commuters
Activity	Strong morning activity signal
Places	Relevant surrounding place categories
Context	Transit, offices or other useful anchors

The recommendation becomes much more useful when the user can see the evidence behind it.

10. BUILD A SMALL VERSION FIRST

LEVEL 1 / BEGINNER

Choose one audience → rank corridors → show a list

LEVEL 2 / INTERMEDIATE

Add activity, places, maps, filters or corridor details

LEVEL 3 / ADVANCED

Let users ask questions in plain English and use LLM + MCP to collect and explain relevant data

MCP = a way for an AI model to use tools or data sources in a structured way.

11. WHERE COULD MCP FIT?

User asks	AI understands	MCP gets the data	Your logic compares	Answer + explanation
-----------	----------------	-------------------	---------------------	----------------------

For example, the AI could request audience information and corridor details, then use those results to produce a shortlist.

REMEMBER MCP is the bridge. The useful product is the answer the user gets from the data.

EXAMPLE 03 / PRODUCT THINKING

12. QUESTIONS YOU COULD LET THE USER ASK

TYPE	EXAMPLE QUESTION
ONE AUDIENCE	“Where are morning commuters most relevant?”
ANOTHER AUDIENCE	“Which corridors are more relevant for families?”

AUDIENCE + TIMING	“Where are morning commuters important and morning activity is also high?”
AUDIENCE + PLACES	“Where are hospital workers important, and what is already around them?”
MULTIPLE AUDIENCES	“Which corridors are relevant to both families and weekend visitors?”

13. POSSIBLE EXTENSIONS

- Add a map so users can see recommended corridors geographically.
- Compare two corridors for the same audience.
- Let users select more than one audience and look for overlap.
- Show nearby places and anchors after a corridor is selected.
- Add an AI explanation for “Why is this corridor relevant?”
- Create a downloadable audience-to-corridor report.

THE IMPORTANT PART Each extension should make the recommendation more useful — not simply more complicated.

14. THINK FROM THE USER’S PERSPECTIVE

USER	Business team, marketer, researcher or entrepreneur
QUESTION	Where should I look for the audience I care about?
EVIDENCE	Audience score + activity + places + corridor context
OUTPUT	A ranked list of relevant corridors with reasons
DECISION	Which corridor should I investigate next?

15. IMPORTANT DATA NOTE

Audience scores are signals for comparison, not exact counts of people. Daypart information is a relative activity indicator, not direct foot-traffic volume. Some behavioral and whitespace measures are based on expert or contextual assessment.

USE CAREFUL LANGUAGE

“This corridor shows stronger relevance for this audience.”

AVOID

“This corridor contains the most people from this audience.”

16. YOUR CHALLENGE

BUILD THIS IDEA IN YOUR OWN WAY

Create a tool that answers:

“Given an audience I care about, which corridors should I explore, and what makes them relevant?”

Start with one audience. Make one useful recommendation. Then add more context.

17. TRY DIFFERENT AUDIENCES

MORNING COMMUTERS	FAMILIES	HOSPITAL WORKERS	STUDY GROUPS
-------------------	----------	------------------	--------------

Pick one audience, then ask what extra information would help you make a better recommendation. The same tool can become useful for many different questions.

18. A GOOD FIRST BUILD

1 SELECT Choose one audience	2 COMPARE Rank a few corridors	3 EXPLAIN Show why they stand out
---------------------------------	-----------------------------------	--------------------------------------

You do not need a complex recommendation engine. A clear shortlist with useful reasons is already a product.

21. REMEMBER

START SMALL One audience → one useful shortlist	ADD CONTEXT Use places, activity and corridor details when helpful	STAY GROUNDED Be clear about what is measured, scored or estimated
--	---	---

AUDIENCE → CORRIDOR → CONTEXT → RECOMMENDATION

Start with one useful answer. Then build from there.
